Missing Data  
&  
Causality

# Questions to ask

**Observational Questions** (*What is?*)

„What if we see  $A$ “

$$P(y|A)$$

**Action Questions** (*What if?*)

„What if we do  $A$ ?“

$$P(y|do(A))$$

**Counterfactual Questions** (*Why?*)

„What if we did things differently?“

$$P(y_{\neg A}|A)$$

**Options**

„With what probability?“

Causal Hierarchy

The diagram illustrates the Causal Hierarchy with four main components arranged in a 2x2 grid. At the bottom center is a light blue oval labeled 'Causal Hierarchy'. Arrows point from this oval to each of the four components: a vertical arrow to 'Observational Questions' (top left), a vertical arrow to 'Options' (bottom right), a diagonal arrow to 'Action Questions' (middle left), and a diagonal arrow to 'Counterfactual Questions' (middle right). Each component includes a title, a question, and a probability expression.

# Structure

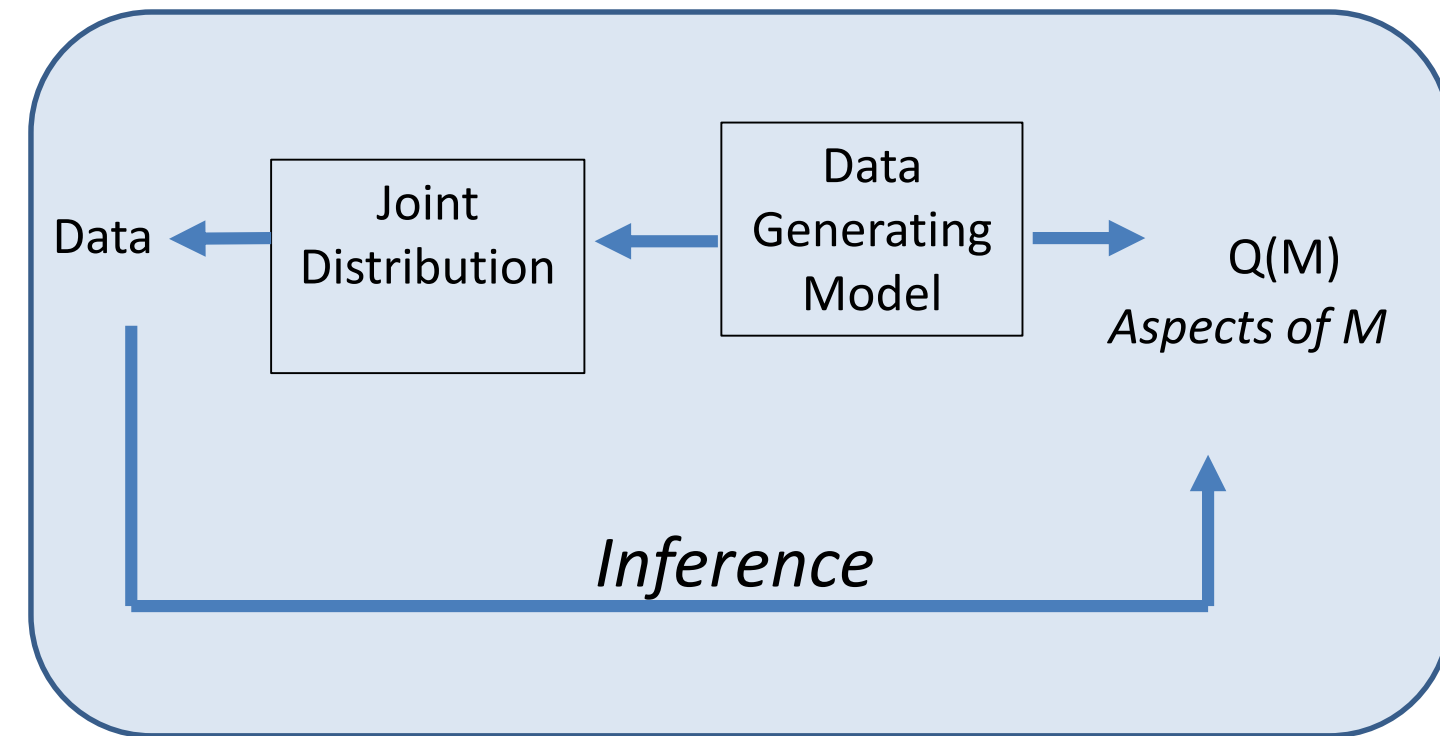

*What is? / What if?*

## Missing Data:

- Missingness as a function
- Patterns vs. Mechanisms
- Naive Imputation
- Multiple Imputation

*What if? / Why?*

## Causality:

- Data Generating Models
- Acyclic Graphical Models
- PC Algorithm

# Data as a function

- Let  $Y$  be a population with the values  $y_i = (y_{i1}, y_{i2}, \dots, y_{ik})$  with  $i \in Y$
- The propability to draw a unit  $i$ , is  $f(y_i; \theta)$  with  $\theta$  indicating the parameter vector
- The observed part of  $Y$  can be denoted as  $Y_{obs}$  and the missing one as  $Y_{mis}$ , so that  $Y = (Y_{obs}, Y_{mis})$  with the joint distribution  $f(y_{obs}, i, y_{mis}; \theta)$  for each unit

# Missingness as a function

- Let  $R$  be an **indicator variable** with unit  $i$  which is  $f(r; \xi)$  distributed

$$R_{i,j} = \begin{cases} 1, & \text{if } Y \text{ observed with unit } i \\ 0 & \text{otherwise} \end{cases}$$

- The **joint distribution** of  $R$  and  $Y$  is

$$f(y, r, \theta, \xi) = f(y; \theta) f(r|y; \xi, \theta), (\theta, \xi) \in \Omega_{\theta, \xi}$$

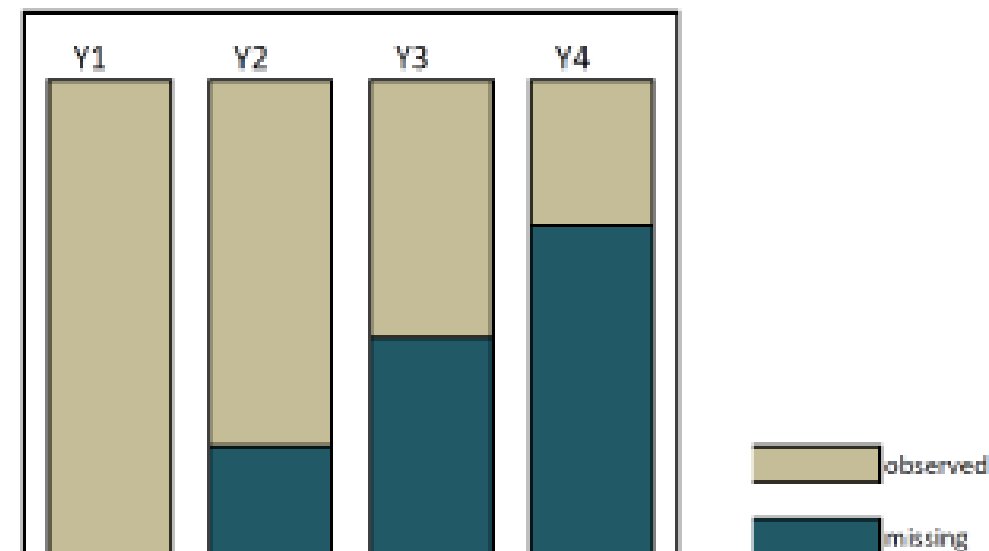

- The **likelihood** of a unit  $\xi \in \Omega$  is

$$L(\theta, \xi; y_{obs}, r) = \int f(y_{obs}, y_{mis}, r; \theta, \xi) dy_{mis}$$

$$\int f(y_{obs}, y_{mis}; \theta) f(r|y_{obs}, y_{mis}; \theta) f(r|y_{obs}, y_{mis}; \xi, \theta) dy_{mis}$$

Index	Y1	Y2	R1	R2
1	$y_{11}$	$y_{12}$	1	1
2	$y_{21}$	$y_{22}$	1	1
3	$y_{31}$		1	0
4	$y_{41}$		1	0
5			0	0

# Patterns vs. Structures

*A pattern can be very non-random, but the mechanism might still be random!*

# Notation for Missing Data mechanisms

**Not Missing at Random (NMAR)**

$$f(r|y; \xi) = f(r|y_{obs}, y_{mis}; \xi)$$

**Missing at Random (MAR)**

$$f(r|y; \xi) = f(r|y_{obs}, y_{mis}; \xi) = f(r|y_{obs}; \xi) \forall Y_{mis}$$

**Missing Completely at Random (MCAR)**

$$f(r|y; \xi) = f(r|y_{obs}, y_{mis}; \xi) = f(r; \xi) \forall Y$$

**Assumption:**

Variation freedom:  $\theta$  and  $\xi$  are distinct/independent  $\rightarrow f(r|y; \xi, \theta) = f(r|y; \xi)$

Under **MAR** and variation freedom, the missing data mechanism is ignorable since the „observed-data“ likelihood of any unit resolves to:

$$L(\theta, \xi; y_{obs}, r) = \int f(y_{obs}, y_{mis}; \theta) f(r|y_{obs}, y_{mis}; \theta, \xi) dy_{mis} = f(r|y_{obs}; \xi) \int f(y; \theta) dy_{mis}, \theta \in \Omega_{\theta}, \xi \in \Omega_{\xi}$$

# Recognizing Mechanisms

IQ	Job performance ratings II			
	Complete	MCAR	MAR	MNAR
78	9	—	—	9
84	13	13	—	13
84	10	—	—	10
85	8	8	—	—
87	7	7	—	—
91	7	7	7	—
92	9	9	9	9
94	9	9	9	9
94	11	11	11	11
96	7	—	7	—
99	7	7	7	—
105	10	10	10	10
105	11	11	11	11
106	15	15	15	15
108	10	10	10	10
112	10	—	10	10
113	12	12	12	12
115	14	14	14	14
118	16	16	16	16
134	12	—	12	12

## MCAR:

Missingness neither conditional on  $Y_{\text{obs}}$  nor  $Y_{\text{mis}}$   $\rightarrow$  random

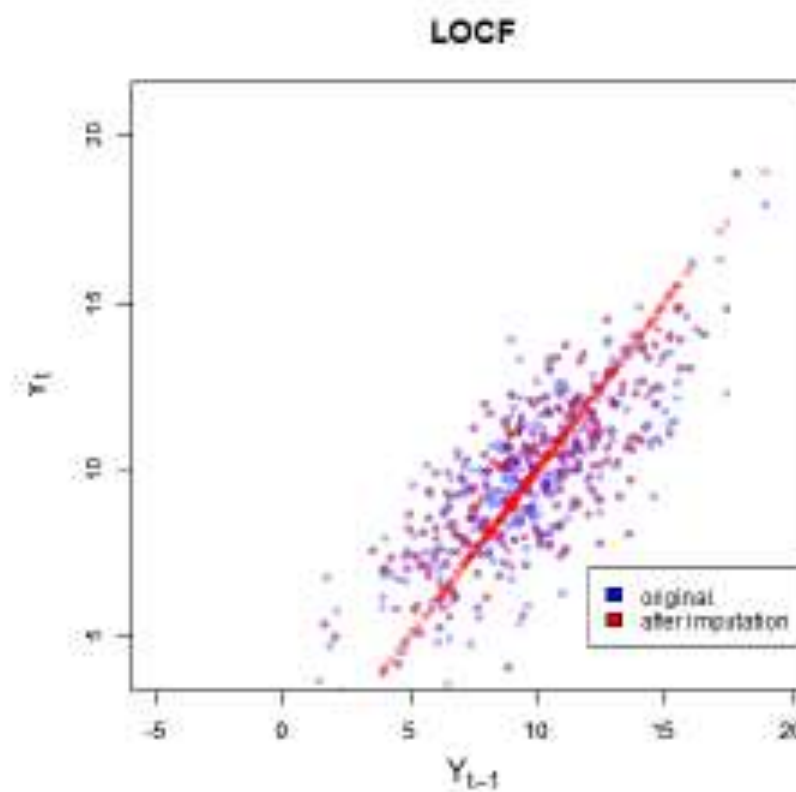

## MAR:

Missingness conditional on  $Y_{\text{obs}}$  but not  $Y_{\text{mis}}$

## MNAR:

Missingness conditional on  $Y_{\text{mis}}$

# To MI or not to MI...

## When does it work?

- Crosstabs
- Correlations
- Descriptive Statistics

## Potential Pitfalls:

- Skewed Distributions
- Reduced variance / Confidence Intervals
- Hypothesis testing
- Model uncertainty
- Inferential Statistics

Even if you're able to perform multivariate analysis with a naively imputed dataset you do not account for **model uncertainty**.

# Ba(ye)sics of Multiple Imputation

Common to all approaches:

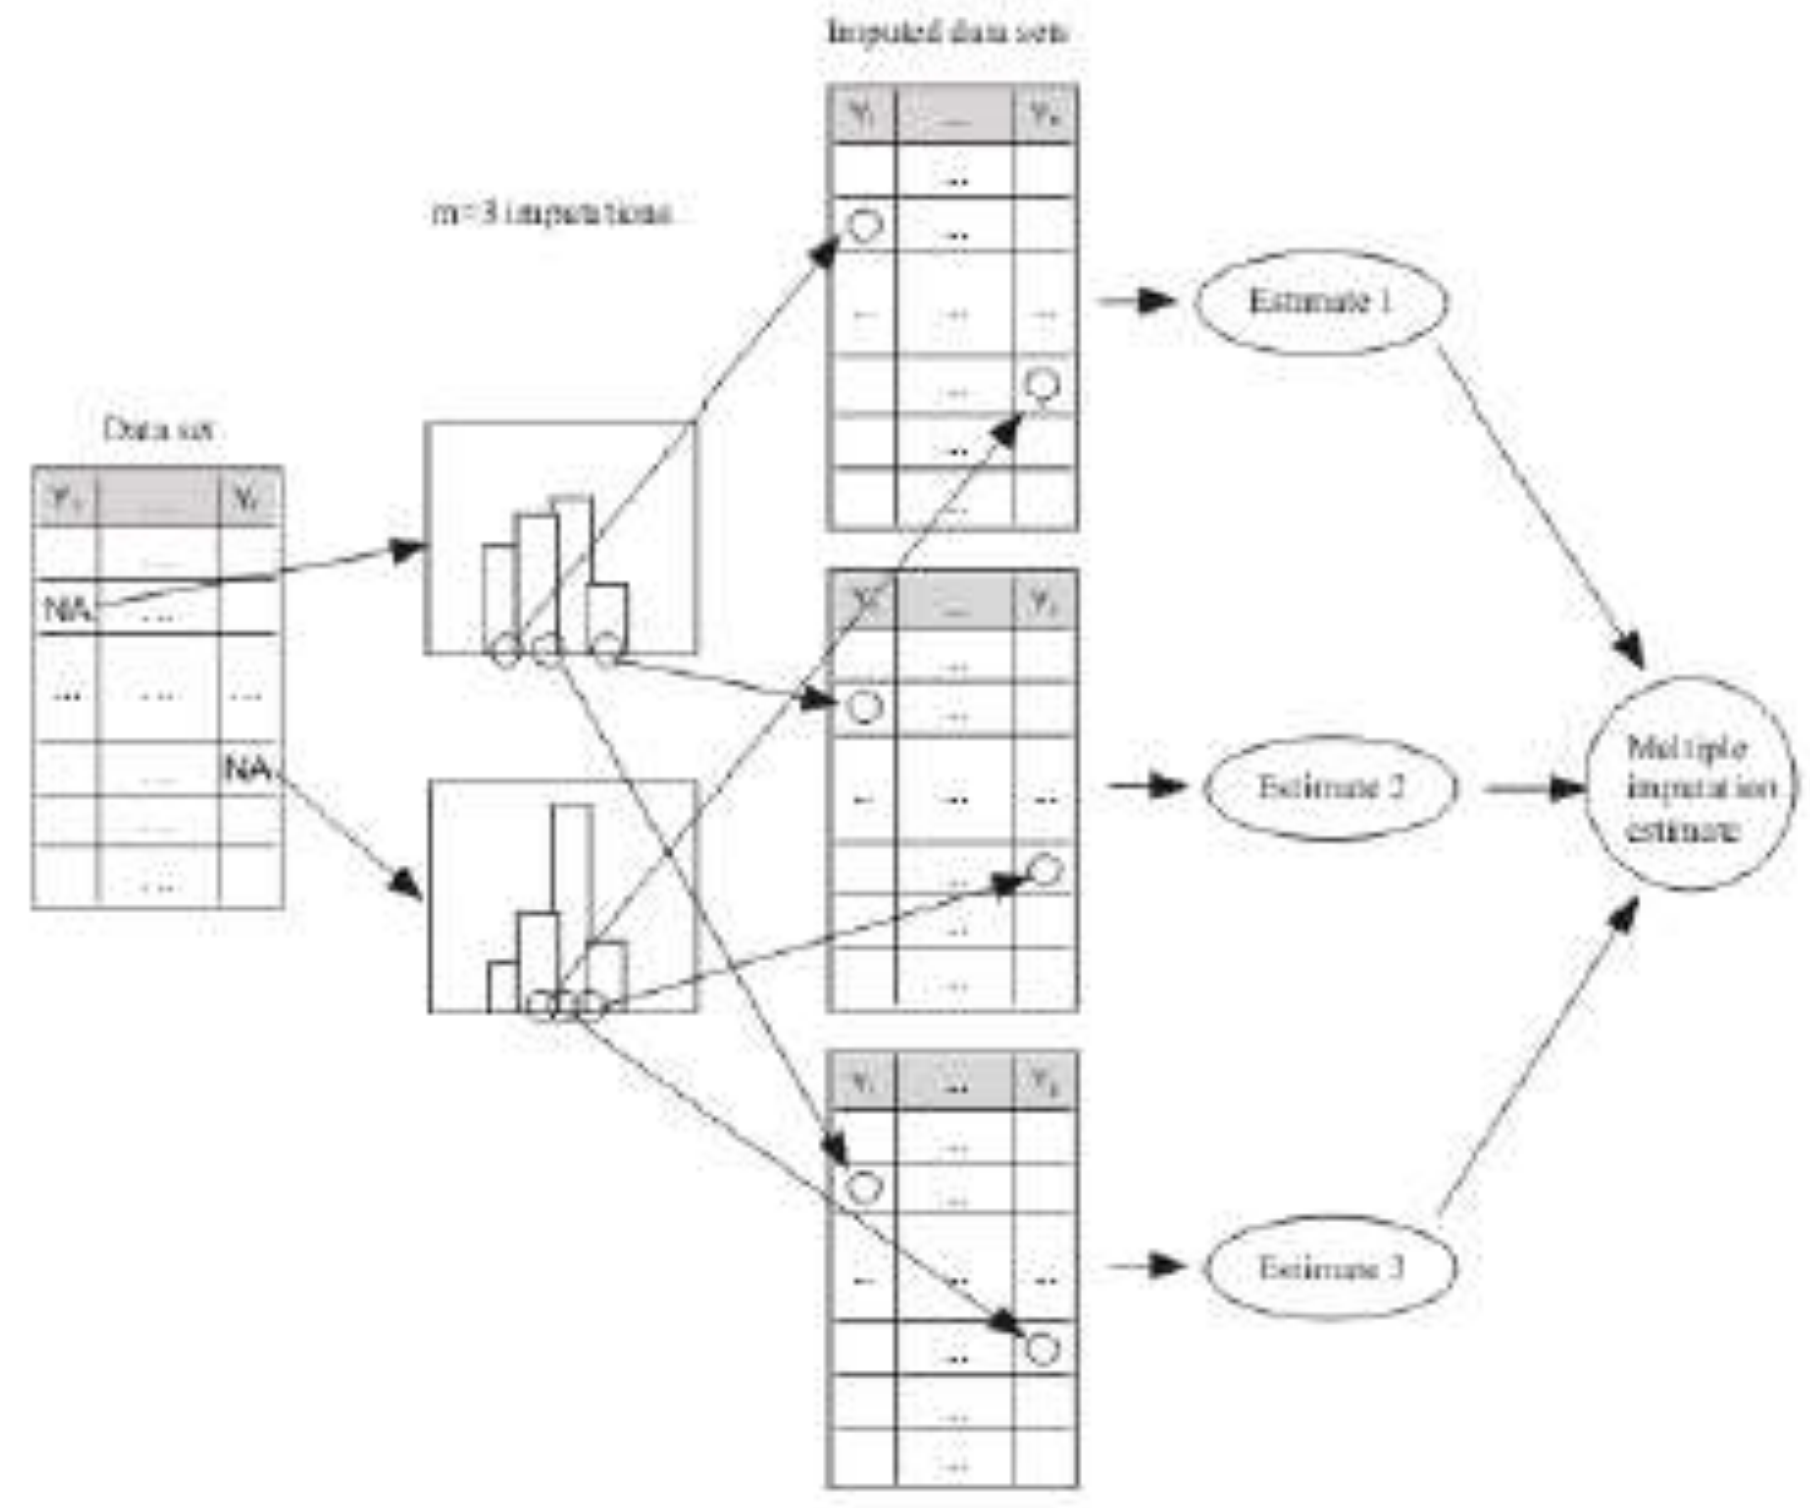

**Produce several uniquely imputed datasets and calculate the mean.**

Inferential MI:

- Regression
- Nearest Neighbour
- Last Observation Carried Forward

Bayesian MI:

- Draw from a Posterior Predictive Distribution

# Ba(ye)sics of Multiple Imputation

$f(\theta) =:$  Prior distribution

$f(\theta|y) =:$  Posterior distribution

$f(y|\theta) = L(\theta;y) =:$  Likelihood

$f(y) =:$  Marginal distribution of the data

Posterior Predictive Distribution for MI:

$$f(y_{\text{mis}}|y_{\text{obs}}) = \int_{\Omega} f(\psi|y_{\text{obs}})f(y_{\text{mis}}|\psi, y_{\text{obs}})d\psi$$

Posterior-Step:

$$\tilde{\psi} \sim f(\psi|y_{\text{obs}})$$

Imputation-Step

$$y_{\text{mis}} \sim f(y_{\text{mis}}|\tilde{\psi}, y_{\text{obs}})$$

Interchanging draws from  
the observed-data posterior  
and the conditional  
predictive distribution yield  
random draws from  
 $f(y_{\text{mis}}|y_{\text{obs}})$

# Questions to ask

**Observational Questions** (*What is?*)

„What if we see A“

$$P(y|A)$$

**Action Questions** (*What if?*)

„What if we do A?“

$$P(y|do(A))$$

**Counterfactual Questions** (*Why?*)

„What if we did things differently?“

$$P(y_{\neg A}|A)$$

**Options**

„With what propability?“

Causal Hierarchy

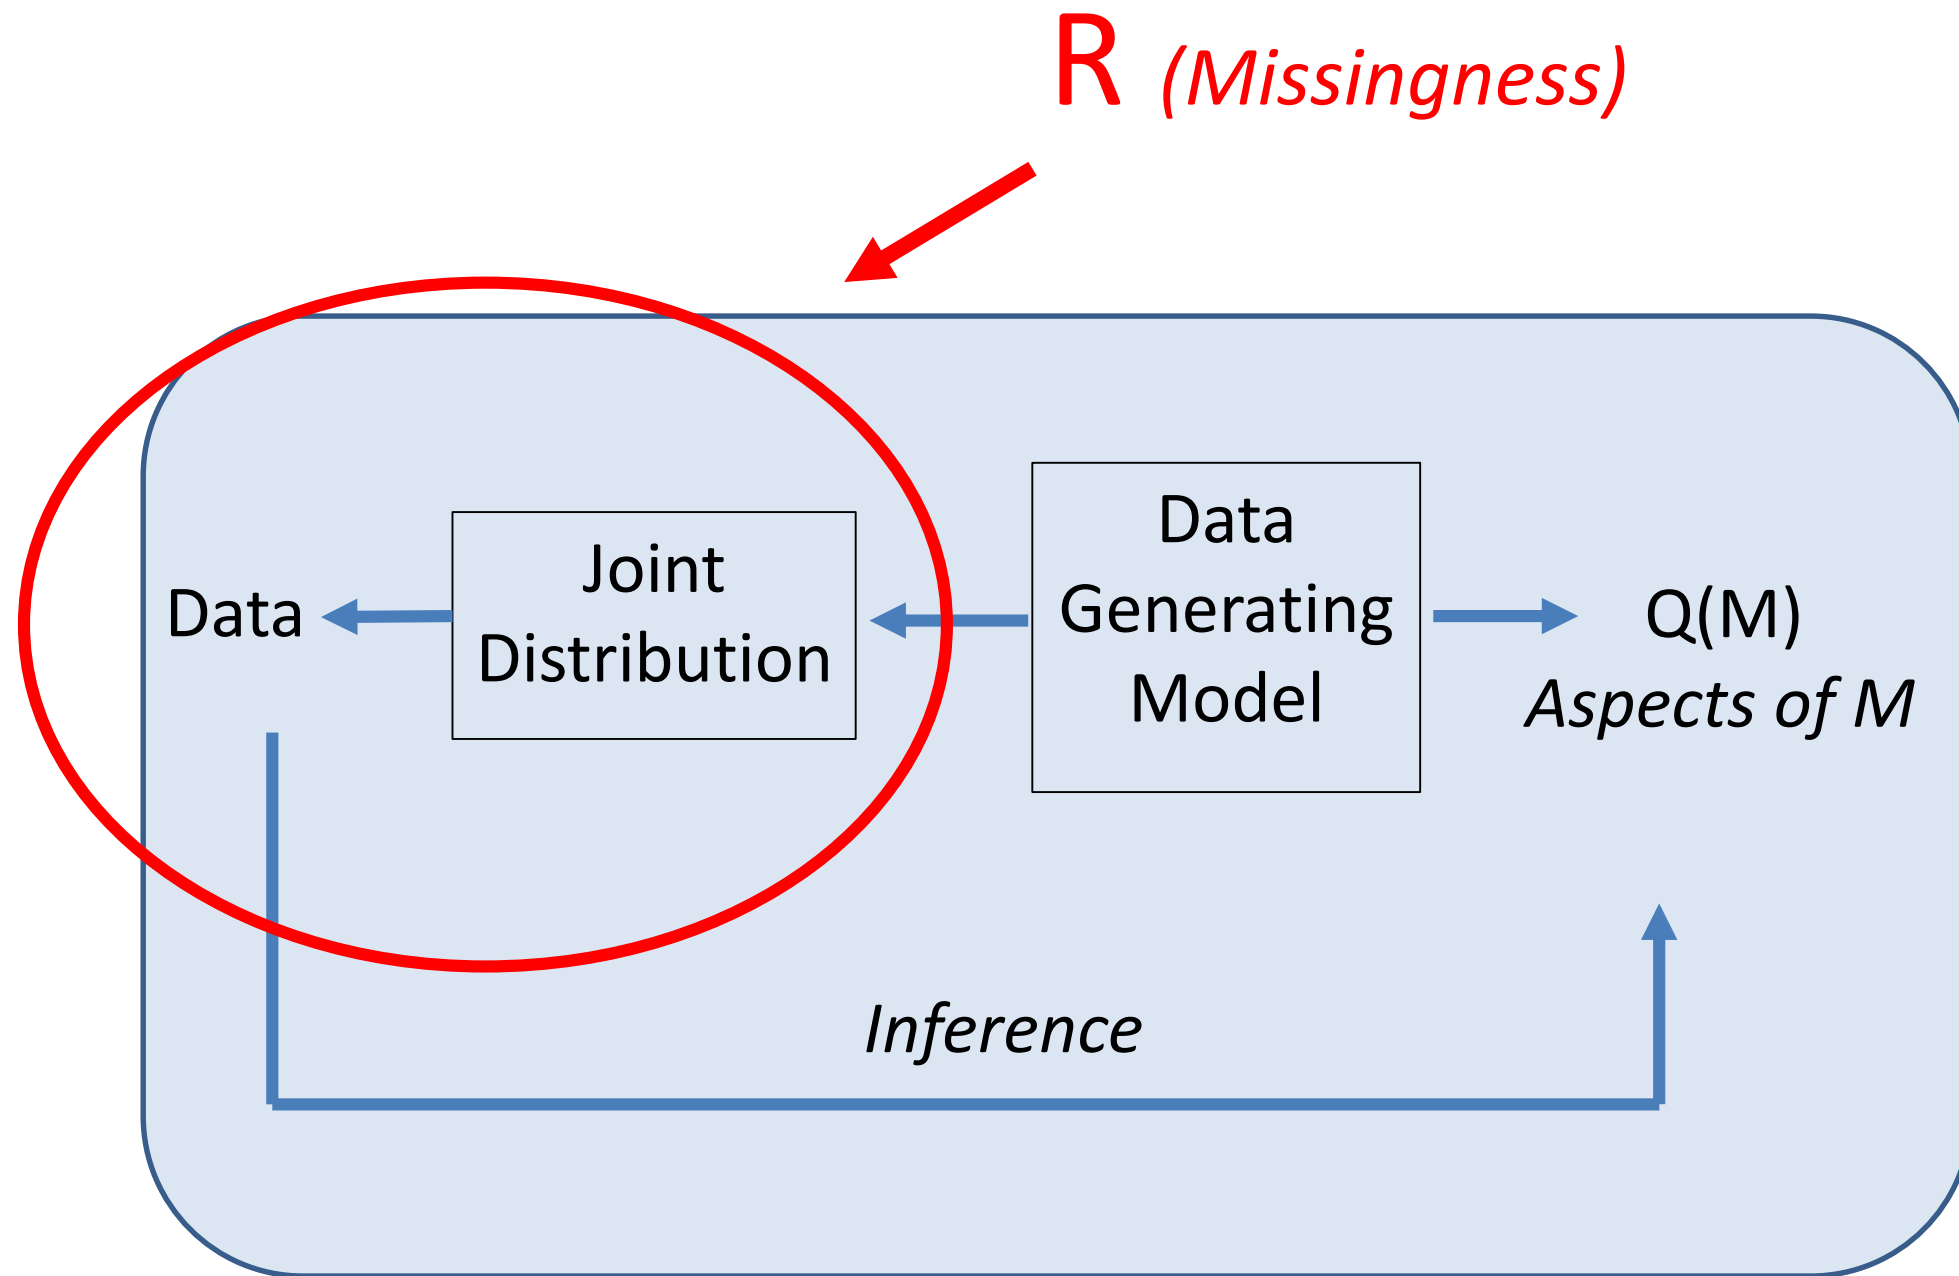

The diagram illustrates the Causal Hierarchy with three levels of questions. At the top left is 'Observational Questions (What is?)' with the example '„What if we see A“' and the probability expression  $P(y|A)$ . A vertical blue arrow points down to 'Action Questions (What if?)' with the example '„What if we do A?“' and the probability expression  $P(y|do(A))$ . A diagonal blue arrow points from the Action level up to 'Counterfactual Questions (Why?)' at the top right, which includes the example '„What if we did things differently?“' and the probability expression  $P(y_{\neg A}|A)$ . A vertical blue arrow points down from the Counterfactual level to 'Options' with the example '„With what propability?“'. At the bottom center, a light blue oval contains the text 'Causal Hierarchy'.

**„Correlation does not imply  
causation.**

**—**

**But there is no correlation  
without causation.“**

# Basic Model of Causality

**Fundamental laws of causal inference:**

## 1. Law of counterfactuals

$$Y_x(u) = Y_{M_x}(u)$$

→ M generates and evaluates all counterfactuals

## 2. Law of Conditional Independence

$$(X \perp\!\!\!\perp Y | Z)_{G(M)} \rightarrow (X \perp\!\!\!\perp Y | Z)_{P(V)}$$

→ Separation in model entails independence in distribution

**What do you think are good rules for choosing control variables?**

Control für Z if...

- Z associated with Y (Outcome)
- Z associated with X (Covariate)
- Unaffected by X and associated with X and Y

# Structural Causal Models

## Acyclic Causal Graphs:

- Show causal relationships between different variables
- No circle-connections
- Assuming you measured all relevant variables
- There can be several markov-equivalent causal models

## Normal Inference:

Creating one model and testing if it fits certain requirements

## Causal Inference:

Searching for all plausible causal models

# Constraint Based CI (PC-Algorithm)

Search for Markov Equivalent Classes  
(same d-separations, nodes)

## 2 Main Steps:

1. Learn Skeleton Graph with undirected edges  
→ Start with fully connected graph and test for conditional independence
2. Direct the edges to get causal model  
→ Use of Additive Noisew Modelling  
(lowest dependence between potential cause and its residual when predicting the effect)

---

**Algorithm 1:** Step 1 of the original-PC algorithm: learning the skeleton

---

**Input:** Dataset  $D$  with a set of variables  $V$ , and significant level  $\alpha$   
**Output:** The undirected graph  $G$  with a set of edges  $E$   
Assume all nodes are connected innitally  
Let depth  $d = 0$   
**repeat**  
  **for** each ordered pair of adjacent vertices  $X$  and  $Y$  in  $G$  **do**  
    **if**  $(|adj(X, G) \setminus \{Y\}| \geq d)$  **then**  
      **for** each subset  $Z \subseteq adj(X, G) \setminus \{Y\}$  and  $|Z| = d$  **do**  
        Test  $I(X, Y|Z)$   
        **if**  $I(X, Y|Z)$  **then**  
          Remove edge between  $X$  and  $Y$   
          Save  $Z$  as the separating set of  $(X, Y)$   
          Update  $G$  and  $E$   
          **break**  
        **end**  
      **end**  
    **end**  
  **end**  
  Let  $d = d + 1$   
**until**  $|adj(X, G) \setminus \{Y\}| < d$  for every pair of adjacent vertices in  $G$ ;
